Extinct fish from overfishing

Which fish are endangered due to overfishing. How many fish die a year from overfishing. How many species of fish have gone extinct due to overfishing.

Removal of a spy of water fish at a rate that the species can not reset 400 tons of monkey monkey captured by a Chilean bag, fish fishing fishing is The removal of a fish species from a water body at a rate that the species can not refuel, resulting in these species that become subpopulated in this area. Overfishing can occur in water bodies of any sizes such as ponds, rivers, lakes or oceans, and can result in resources, reduction of biological growth rates and low biomass levels. Overfishing sustained can lead to a chronic propensation, where the population of fish is not able to sustain itself. Some forms of overfishing, such as the overfishing of sharks, led to the annoyance of all marine ecosystems. [1] Types of overforcement include: overweight growth, recruitment overload, ecosystem overweight. The ability of a fishing to recover from overfishing depends on whether the conditions of the ecosystem are suitable for recovery. Dramatic changes in spies composition may result in an ecosystem change, where other balance energy flows involve different species compositions of those present before the exhaustion of the Original stock of fish. For example, since the trout was overcome, carp can take over in a way that makes it impossible for the trout to restore a reproductive population. Since the growth of global fishing companies after the D   Each of 1950, intensive fishing spread from some concentrated areas to encompass almost all fisheries. The ocean background scraping on the bottom drag is devastating to coral, sponges and other long durable sponges that do not recover quickly, and which provide a habitat for commercial fishing spaces. This destruction changes the functioning of the ecosystem and can permanently alter the composition and biodiversity of the species. ByCatch, the capture of non-intentional sports in the course of fishing, is typically returned to the ocean just to die of injury or exposition. Bycatch represents about a quarter of all sea catches. In the case of shrimp capture, the capture access is five times larger than the caught shrimp. A FAO report in 2020 stated that "in 2017, 34 percent of the world's marine fish stocks were classified as superfesa." [2]: A       "Mititating options include: Government regulation, removal of subsidies, minimizing the impact of fishing, aquaculture and consumer awareness. Scale on overfishing scores range from 1    7; 7 = The highest level of overfishing overfishing stripped many fisheries throughout the world of their actions. The food and agricultural organization of the United Nations estimated in a 2018 report that 33.1% of world fish stocks are subject to overload. [3] The significant overfishing was observed in pranitures. In particular, overfishing of the West Atlantic Ocean from the first few days of the European colonization of the Americas was well documented. [4] The fraction of fish stocks that are within the biologically sustainable levels   
